Introduction

This native is endangered of extinction in Florida (Fig. 1). It forms irregular clumps or shrub-like mounds in sandy soils, and has a very coarse texture. The leaves of Prickly Pear Cactus are inconspicuous, however the plate-like sections of the stem are often thought of as leaves. These plate-like sections are actually modified stems and reach a length of 2 to 6 inches. Stem sections remain green with age and are covered with 3-inch-long spines. Very minute spines (glochids) are located in the numerous areoles. The larger spines are quite painful, however the minute spines cause a lot of irritation if they are captured in clothing or attach onto the skin surface.

Use and Management

When the flowers of this plant are produced in large numbers, as on vigorously growing individuals, they put on quite a show. The plant will bloom over a period of several weeks, however the individual flowers only last one day. The flowers are cup-shaped, bright red, appear on the outermost plate-like stem sections, and are 2 to 3 inches wide. The showy berries may reach a length of 2 to 3 inches and are red to purple at maturity (mid to late summer). These fruits may be eaten after the spines and glochids have been singed off with fire, and the seeds of the fruits can be roasted for flour.

These plants are well-suited to hot, dry conditions. Prickly Pear Cactus can be used as a specimen in areas a dry, rocky unirrigated landscape. An established row of these makes an impenetrable border for pedestrians.

This plant is drought, salt and heat tolerant. It requires a sunny, well-drained site and is tolerant of sandy, alkaline soils. Prickly Pear will only tolerate wet conditions for a very short period of time.

Propagation is by division because the seeds of many species are difficult to germinate. The plate-like sections can be placed on slightly moist sand to obtain rooting.

Pests and Diseases

Opuntia spp. have no pests nor diseases of great concern. Root rot can be a problem in wet locations.
